

# Capstone Project

Finding the best place for a new Spiritual Development Center in Toronto

## Introduction/Business Problem

Discussion of the problem: “Which Toronto neighborhood is the most ideal to start a new Spiritual Development Center?”

My Canadian client devoted to the problem of spiritual growth and personal development is interested to open the Spiritual Development Center in Toronto. She believes that the Center should be situated in the area popular within active people, involved in sport and a healthy lifestyle. She also thinks that restaurants and coffee shops might negatively affect the spiritual growth of her future students, so the ideal neighborhood for the Center should contain less restaurants than venues related to the active lifestyle.

My client asks wants me to consult her on which locality or neighborhood of Toronto is best suited to start the Spiritual Development Center.

## Target Audience

Similarly to my client, other businesses can be interested to know which Toronto neighbourhoods attract active people. These information can be used for new venue openings and for advertisement targeting of such venues as sport goods shops, healthy food shops, nutritionists, supplement shops, alternative medicine centers and others.

## Data Description:

### Description:

This project relies mainly on the data available from Foursquare and Wikipedia.

Dataset 1: List of postal codes of Toronto along with the boroughs and neighborhoods

Since we focus on Toronto in this project, we will be looking to procure all the demographic information related to city, including all the boroughs and neighborhoods of Toronto along with their associated zip code.

To do this, we rely on the publicly available Wikipedia page for the same, titled List of postal codes of Canada: \_M. As can be seen from the description of the page: “Postal codes beginning with M are located within the city of Toronto in the province of Ontario.”

We will be scraping this data from the Wikipedia page with the help of Python’s pandas and Wikipedia packages.

Dataset 2: Geographical coordinates of the neighborhoods

In order to plot the neighborhoods on the map, we will also be using the geographical co-ordinates of the neighborhoods of Toronto. Although this data can be obtained using the Google Maps Geocoding API, given the unreliability of the package we use data from the following source:

[http://cocl.us/Geospatial\\_data](http://cocl.us/Geospatial_data)

### Dataset 3: Data called from Foursquare API

In this project, we will be leveraging the Foursquare API to obtain the geographical location data of various neighborhoods of Toronto. This data will be used to explore the venues in each of the neighborhoods, which will help us to identify the best possible location for our client's Center.

We will redefine venues categories to satisfy the client's requirement as "Food provider", "Health provider" and "Indifferent" venues.

## Methodology

### Neighbourhoods data pre-processing

After scraping the initial data from Wikipedia, there were some improvements required before it could be used for analysis. Some modifications that were made to it were:

- Dropping all the rows from the derived table where boroughs were not assigned
- Combining different neighborhoods with the same postcode
- For neighborhoods with no name, assigning a borough name to it for the purposes of simplicity
- Concatenating the geospatial coordinates obtained from Dataset 2 to this dataframe.

### Redefining venues categories

Accordingly to the client's requirements, we need to redefine venues categories as "Food provider", "Health provider" and "Indifferent". To do that, we formed three lists of the Foursquare venue categories using corresponding keywords for "Food provider" for "Health provider". Then we replace the Foursquare venue categories by there new categories.

- *The list of keywords for the selecting "Food provider" category:* restaurant, coffee, spot, caf (excl: gaming), snack, bistro, pizza, place, joint, noodle, cupcake, candy, bakery, food court, ice cream, diner, , steakhouse, gastropub, creperie, tea, beer, brewery, liquor, deli, cheese, dessert, fish & chips, pub, speakeasy, market (excl: flea), bar, food (excl: health), grocery (excl: organic).
- *The list of keywords for the selecting "Health provider" category:* health, gym, field, park, stadium, sport (excl: bar), court (excl: food), studio (excl: recording), supplement, smoothie, organic, skat, pool, swim, bike, trail, arena.
- Foursquare venue categories not selected as "Food provider" and "Health provider" are defined as "Indifferent" venues.

### Data preparation for the clustering of neighborhoods

To find group of Toronto neighborhoods with satisfactory venue environment, we used k-means clustering. Each Postal Code area (which could contain a few neighbourhoods) was characterized by the proportion of "Food provider", "Health provider" and "Indifferent" venues. These proportions were employed as features for k-mean clustering.

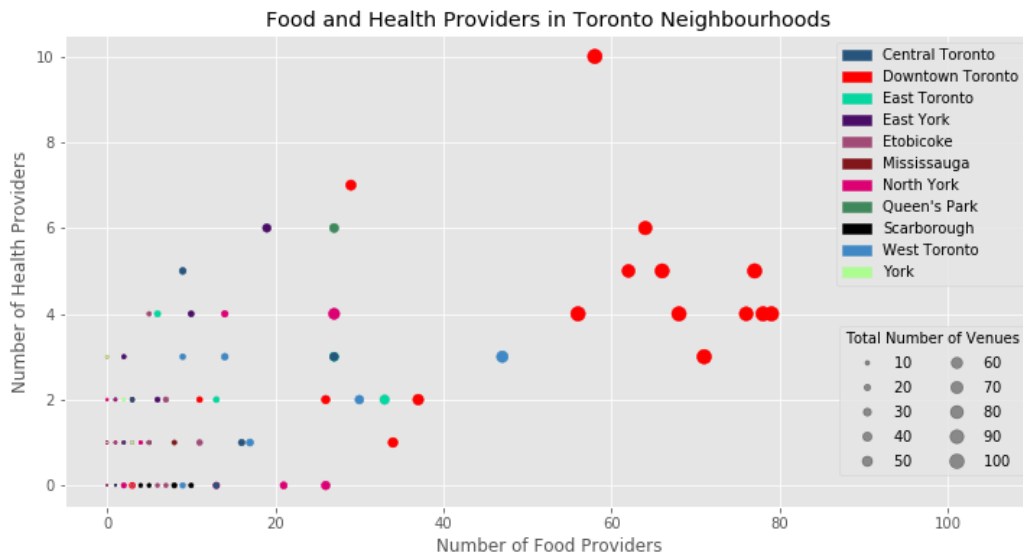

### K-mean clustering of neighborhoods

The reasonable number of clusters ( $k=3$ ) was selected after manual inspection the results of clustering with different  $k$ . As a selection criterion we used the number of neighbourhoods within the same borough which have been distributed to the same cluster by their proportion of "Food provider", "Health provider" and "Indifferent" venues. These method gives us relatively large areas; each contains few adjoining neighbourhoods.

**Figure 1.** Words clouds representing the Foursquare venue categories redefined to as A: “Food Providers”, B: “Indifferent” venues and C: “Health Providers”

## Data preparation for the clustering of neighborhoods

Each postal code area contained one or few neighbourhoods was characterized by the frequency of “Food provider”, “Health provider” and “Indifferent” venues (Figure 2). Due to the wide difference in total venue numbers between the areas, the data was converted to the proportions of “Food provider”, “Health provider” and “Indifferent” venues in each area.

**Figure 2.** The frequency of “Food provider”, “Health provider” and “Indifferent” venues in the Toronto Postal code areas.

## K-mean clustering of neighborhoods

After manual inspection the results of clustering with different  $k$ ,  $k=3$  was selected as providing the best results. All postal code areas were separated to three clusters. Each cluster contained areas characterized by the same most common venue category: “Food provider”, “Health provider” and “Indifferent” (Figure 3).

## Cluster exploration

### “Food Providers”

The cluster characterized by “Food Providers” as the most common venue category by k-mean algorithm is the largest one, contains 61 postal code areas from 11 Toronto boroughs. The highest proportion of “Health Providers” (10%) was found in the area with postal codes started with M5J, which contains Harbourfront East, Toronto Islands, Union Station neighbourhoods (Table 1). The average “Health/food ratio” in this cluster was equal to 0.15 with highest ratio of 0.8 demonstrated by postal code area: “M8W” corresponding to Alderwood and Long Branch neighbourhoods.

The cluster characterized by “Indifferent” as the most common venue category by k-mean algorithm contains 26 postal code areas from 7 Toronto boroughs. The highest proportion of “Health Providers” (23%) was found in the area with postal code M4R corresponds to North Toronto West neighbourhood (Table 2). The highest “Health/food ratio” in this cluster was 1.5 demonstrated by postal code area: “M4C” corresponding to Woodbine Heights. There are only 10 venues in the neighbourhood with only two “Food Providers” and three “Health Providers”.

Lastly, the cluster characterized by “Health Providers” as the most common venue category contains 16 postal code areas from 8 Toronto boroughs. The highest proportion of “Health Providers” (75%) was found in the areas with postal code M4W and M6C linked to Rosedale neighbourhood in Downtown Toronto and Humewood-Cedarvale in York, correspondingly (Table 3).

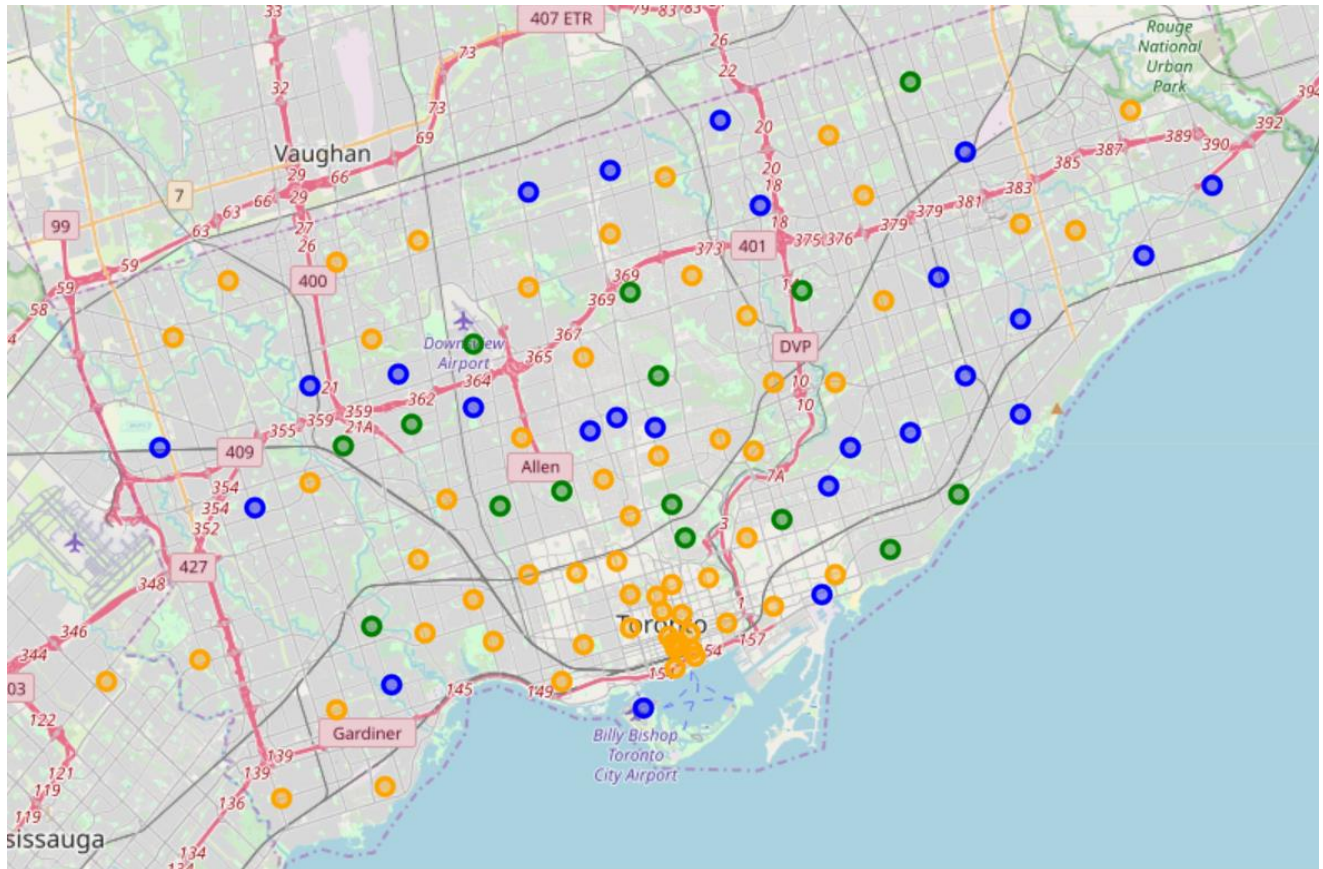

Figure 3. The map of Toronto with postal code areas marked correspondingly to the most common venue category: orange marks, “Food provider”; green marks, “Health provider”; blue marks, “Indifferent” venues. Marks are placed in the geographical centres of each postal code area.

**Table 1.** Postal codes and neighborhoods directed to the cluster characterized by “Food Providers” as the most common venue category by k-mean algorithm, with number of venues, number and proportion of food and health providers and health/food ratio.

Borough	Neighborhood	Postal Code	Venues	1st Most Common Venue	Health Provider (proportion)	Food Provider (proportion)	Health / Food Ratio

## Discussion

The observed clusters allow us to choose the neighbourhoods for the opening of new Spiritual Development Center. It can be situated in York (Caledonia-Fairbanks, Humewood-Cedarvale, Weston) or North York (CFB Toronto, Downsview East, Downsview, North Park, Upwood Park, Parkwoods, York Mills West). However, I would recommend my client to conduct deeper research which include population data in different Toronto neighbourhoods and marketing research data. The modification of methodology by rethinking of influence of the restaurants and food markets on the spiritual development needs might be useful as well.

## Conclusion

Despite the clear and univocal results provided by our research, the decision cannot be made using the limitations of the client's data and requirements.
